

NX CAM Integrated Simulation and Verification

Real-time validation of the part machining process within the NC programming session

Benefits

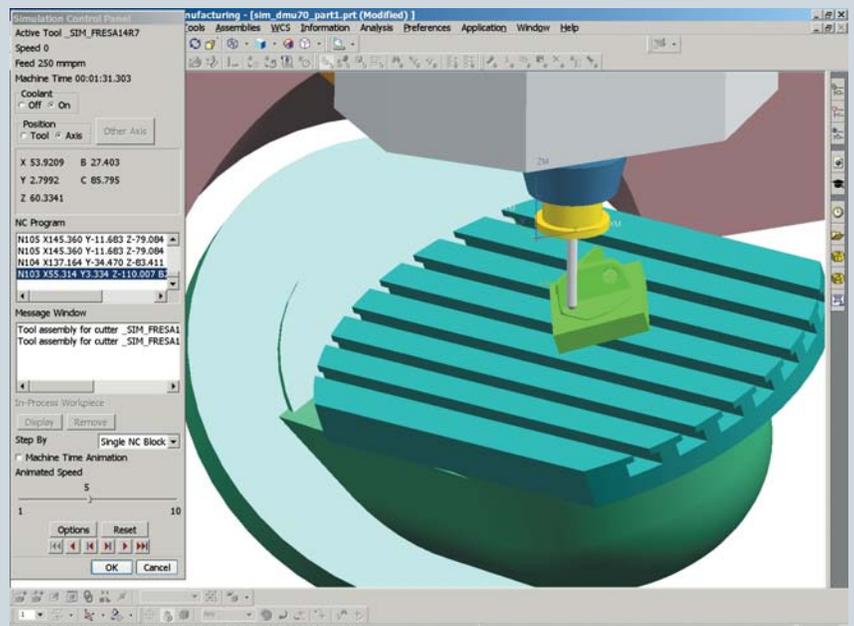

- Checks proposed toolpath validity during CAM session for fast and easy problem identification and change opportunity
- Facilitates faster more efficient processing than conventional try-out methods
- Provides warning capabilities by leveraging automatic collision and checking elements; avoids costly and dangerous errors
- Allows the entire machine operation to be validated – not just the toolpath
- Reduces errors since tooling, fixture and machine geometry only needs to be created once, reducing time and costs

Summary

NX™ CAM Integrated Simulation and Verification (ISV) software is a state-of-the-art application that enables the NC programmer to validate toolpaths and machine motion through digital simulation from within the programming session. The software is modular and covers toolpath and material removal simulation through complete machine tool motion simulation. Using advanced simulation technology and full 3D in-process representations of the part, coupled with gouge and collision checking methods, ISV eliminates the need to tie up expensive production equipment to verify manufacturability. ISV is fully embedded within NX CAM, allowing the simulation process to be simultaneous with programming while facilitating immediate, real-time feedback and validation.

The value of simulation and verification

Being able to simulate and verify a manufacturing process in the digital world can significantly improve the expectation that the task will execute

SIEMENS

NX CAM Integrated Simulation and Verification

Features

- Verification of material removal and simulation of entire machine tool motion
- ISV operation in NX CAM (within the NC programming session)
- Simultaneous collision detection and gouge checking
- Accurate representation of machine tool kinematics and configuration
- Modular software from metal removal verification to full machine tool simulation and the addition of new machines

as planned, with no errors, in the real environment. In the area of NC machining, there are a number of areas that the programmer and manufacturing engineer would frequently wish to validate before running a job on the machine tool. This ranges from a detailed check of the proposed toolpath in terms of complete and correct material removal, without collisions or gouging, to a wider check on the overall machine motion to ensure that limits of travel are not exceeded and that there are no collisions with any part of the machine or fixtures.

Finding these problems early in the planning cycle minimizes schedule slippages, reprogramming time and the risk of creating scrap parts.

NX CAM ISV products

The ISV family of products within the NX CAM portfolio provides both toolpath and full machine tool simulation and verification.

The software is modular, with the entry level module, CAM Visualize, providing toolpath and material removal verification. Machine Tool Simulation provides the ability to run simulations of the machining process within the context of a complete machine tool. Advanced Machine Tool Simulation adds the tools necessary to create new machine models with full kinematic definition for use in the simulation module.

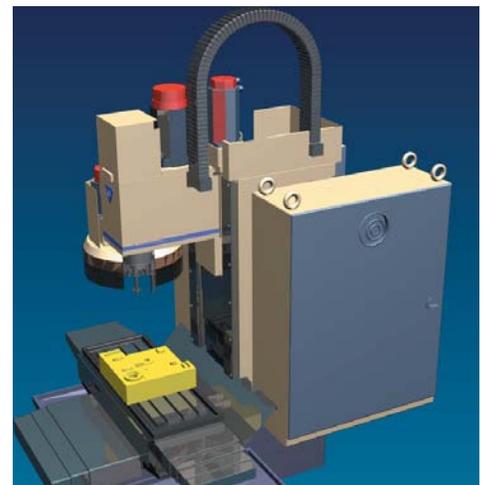

ISV products run within the NX CAM programming environment. This allows the programmer to run verification sequences as an integral part of the programming task. It avoids both the need to export data out of the programming system and having to create and maintain duplicate machine and tooling models for use in separate, external verification packages.

CAM Visualize

The ISV entry-level module, CAM Visualize, provides the CAM programmer with the ability to simulate machining operations with integrated verification of material removal and toolpath validation that is available during the programming session.

In addition to verifying the toolpath, CAM Visualize creates an accurate representation of the in-process workpiece to determine and display the current state of the machined part. The system allows the user to make measurements of stock and tooling and to visualize noncutting moves.

During the simulation, collisions and gouges can be displayed simultaneously. Collision detection considers the tool and the tool holder interacting with the workpiece, fixtures and other components of the machine tool and warns the user about possible collisions. Users no longer need to rely on visual inspection of the animation in order to detect possible collisions.

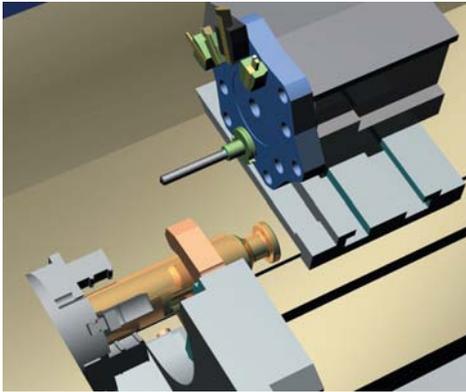

The user is able to access and display tooling and fixtures from the integrated libraries available to NX CAM, including Teamcenter® software's Resource Manager.

Machine Tool Simulation

The Machine Tool Simulation module provides users with the capability to simulate a complete machining environment. This enables the programmer to check the validity of the toolpath within the context of the complete machine tool. This simulation helps ensure that the key characteristics of the machine are not being violated, while providing a more thorough analysis of the proposed machining process. The

simulation includes all controller-dependent motions – for example, table rotation, cycles, macros and specific functionality triggered by the NC program (G and M codes). The software can accurately simulate machine- and controller-specific events, and the user can simulate an operation, a group of operations or the entire NC program.

The Machine Tool Simulation module includes a library of the most common machine tool/kinematics configurations available. For these machines, generic controllers (machine controller drivers) are supplied. Users are able to simulate the most common machining events, and the machine sizes can be edited.

Advanced Machine Tool Simulation

The advanced module within the NX CAM ISV product set provides all of the capabilities that Machine Tool Simulation offers plus the ability to define or modify machine configurations and/or driver characteristics. The module includes the machine tool builder and the machine tool driver components of the machine tool simulation solution. The machine tool builder allows users to create their own machine tool definitions with geometry, linkages, kinematics and tooling. The machine tool driver is used to define machine controller drivers for the customizable virtual NC driver in the Advanced Machine Tool Simulation

software. The module includes an interface to NX CAM Post Builder, so that machine controller drivers can be generated automatically from the specifications provided to the post builder. In order to provide the most reliable simulation possible, Siemens PLM Software works with NC machine and controller partners to integrate software models of popular machine and controller types.
